HPC Architectures

Types of resource currently in use

Outline

- Shared memory architectures
- Distributed memory architectures
- Distributed memory with shared-memory nodes
- Accelerators
- What is the difference between different Tiers?
 - Interconnect
 - Software
 - Job-size bias (capability)

Shared memory architectures

Simplest to use, hardest to build

Shared-Memory Architectures

- Multi-processor shared-memory systems have been common since the early 90's
 - originally built from many single-core processors
 - multiple sockets sharing a common memory system
- A single OS controls the entire shared-memory system
- Modern multicore processors are just shared-memory systems on a single chip
 - can't buy a single core processor even if you wanted one!

Symmetric Multi-Processing Architectures

• All cores have the same access to memory, e.g. a multicore laptop

Non-Uniform Memory Access Architectures

Cores have faster access to their own local memory

Shared-memory architectures

- Most computers are now shared memory machines due to multicore
- Some true SMP architectures...
 - e.g. BlueGene/Q nodes
- ...but most are NUMA
 - Program NUMA as if they are SMP details hidden from the user
 - all cores controlled by a single OS
- Difficult to build shared-memory systems with large core numbers (> 1024 cores)
 - Expensive and power hungry
 - Difficult to scale the OS to this level

Distributed memory architectures

Clusters and interconnects

Multiple Computers

 Each selfcontained part is called a node.

> each node runs its own copy of the OS

Distributed-memory architectures

- Almost all HPC machines are distributed memory
- The performance of parallel programs often depends on the *interconnect* performance
 - Although once it is of a certain (high) quality, applications usually reveal themselves to be CPU, memory or IO bound
 - Low quality interconnects (e.g. 10Mb/s 1Gb/s Ethernet) do not usually provide the performance required
 - Specialist interconnects are required to produce the largest supercomputers. *e.g.* Cray Aries, IBM BlueGene/Q
 - Infiniband is dominant on smaller systems.
- High bandwidth relatively easy to achieve
 - low latency is usually more important and harder to achieve

Distributed/shared memory hybrids

Almost everything now falls into this class

archer

- In a real system:
 - each node will be a shared-memory system
 - e.g. a multicore processor
 - the network will have some specific topology
 - e.g. a regular grid

Hybrid architectures

rcher

- Now normal to have NUMA nodes
 - e.g. multi-socket systems with multicore processors
- Each node still runs a single copy of the OS

Hybrid architectures

- Almost all HPC machines fall in this class
- Most applications use a message-passing (MPI) model for programming
 - Usually use a single process per core
- Increased use of hybrid message-passing + shared memory (MPI+OpenMP) programming
 - Usually use 1 or more processes per NUMA region and then the appropriate number of shared-memory threads to occupy all the cores
- Placement of processes and threads can become complicated on these machines

Example: ARCHER

• ARCHER has two 12-way multicore processors per node

- 2 x 2.7 GHz Intel E5-2697 v2 (Ivy Bridge) processors
- each node is a 24-core, shared-memory, NUMA machine
- each node controlled by a single copy of Linux
- 4920 nodes connected by the high-speed ARIES Cray network

Accelerators

How are they incorporated?

Including accelerators

- Accelerators are usually incorporated into HPC machines using the hybrid architecture model
 - A number of accelerators per node
 - Nodes connected using interconnects
- Communication from accelerator to accelerator depends on the hardware:
 - NVIDIA GPU support direct communication
 - AMD GPU have to communicate via CPU memory
 - Intel Xeon Phi communication via CPU memory
 - Communicating via CPU memory involves lots of extra copy operations and is usually very slow

ARCHER KNL

- 12 nodes with Knights Landing (Xeon Phi) recently added
- Each node has a 64-core KNL
 - 4 concurrent hyper-threads per core
 - Each node has 96GB RAM and each KNL has 16GB on chip memory

- The KNL is self hosted, i.e. in place of the CPU
 - Parallelism via shared memory (OpenMP) or message passing (MPI)
 - Can do internode parallelism via message passing
- Specific considerations needed for good performance

Comparison of types

What is the difference between different tiers?

HPC Facility Tiers

 HPC facilities are often spoken about as belonging to Tiers

Summary

- Vast majority of HPC machines are shared-memory nodes linked by an interconnect.
 - Hybrid HPC architectures combination of shared and distributed memory
 - Most are programmed using a pure MPI model (more later on MPI)
 does not really reflect the hardware layout
- Accelerators are incorporated at the node level
 - Very few applications can use multiple accelerators in a distributed memory model
- Shared HPC machines span a wide range of sizes:
 - From Tier 0 Multi-petaflops (1 million cores)
 - To workstations with multiple CPUs (+ Accelerators)
